ABSTRACT

12 Deadly and dangerous heat waves are increasing with global climate change.

13 Public forecasts and warnings are a primary public health strategy. How-

14 ever, several factors affecting heterogeneity in the urban thermal environment

15 caused by land cover effects may impact the efficacy of such strategies. The

16 emergence of more frequent and widely distributed sources of data on urban

17 temperature provide the opportunity to investigate the specificity of the cur-

18 rent National Weather Service Warnings, and to improve their accuracy and

19 precision. In this work, temperatures from distributed public weather sta-

20 tions, NWS heat advisories and warnings, and land surface temperature im-

21 agery throughout two large metropolitan areas, Atlanta and Chicago, during

22 the summers from 2006-2012 are considered. We first investigate the spatial

23 variability in hazardous temperatures and agreement with advisories issued

24 by the NWS and second examine the potential for a widely available thermal

25 imagery product to replicate National Weather Service heat warnings.

²⁶ **1. Introduction**

²⁷ The potential for future extreme heat events that pose danger to human health is increasing with
²⁸ global climate change. As James Hansen and colleagues at NASA's Goddard Institute for Space
²⁹ Studies put it, we have been loading the climate dice for the last 30 years, increasing the likelihood
³⁰ of meteorological events that used to occur once every hundred years. Models and recent historical
³¹ records echo this sentiment with data and the recent news that atmospheric CO₂ concentrations
³² passed 400ppm for the first time in 3 million years imply that these trends are likely to continue.
³³ Early and accurate warnings are a crucial component for adapting to more frequent hazardous heat
³⁴ events.

³⁵ In this work we consider temperatures from distributed public weather stations, NWS heat ad-
³⁶ visories and warnings, and land surface temperature imagery throughout two large metropolitan
³⁷ areas, Atlanta and Chicago, during the summers from 2006-2012. We first investigate the spatial
³⁸ variability in hazardous temperatures and agreement with advisories issued by the NWS and sec-
³⁹ ond examine the potential for a widely available thermal imagery product to replicate National
⁴⁰ Weather Service heat warnings.

⁴¹ **2. Background**

⁴² The frequency, duration, areal coverage, and intensity of heat waves are expected to increase
⁴³ for most populated places because of global climate change[1, 2]. Such events have caused major
⁴⁴ episodic mortality, including an estimated 70,000 excess deaths in Europe 2003 [3] and more
⁴⁵ than 55,000 in Russia during July and August of 2010 [4, 5]. In many places, early warning
⁴⁶ systems are a key, if not the primary, component of measures for avoiding heat related deaths and
⁴⁷ illness. In the United States the National Weather Service (NWS) issues such warnings. In this
⁴⁸ work we are concerned with the spatial resolution and specificity of the issued warnings. The

⁴⁹ predictions for urban areas, in particular, could be improved given that cities are typically hotter
⁵⁰ than surrounding areas, concentrate people, and demonstrate great variability in temperatures and
⁵¹ population vulnerabilities.

⁵² *a. Adaptation Strategies*

⁵³ The relationship between heat and health is well-understood and known to change over time
⁵⁴ and with location and population characteristics. Future changes in climate will increase adverse
⁵⁵ health impacts [6, 7]. Adapting to changes in extreme heat events has followed three strategies:
⁵⁶ identifying vulnerable populations, and ensuring access to mechanical cooling (air conditioning),
⁵⁷ and implementing early warning systems.

⁵⁸ Several studies using large population data sets and several summers of data demonstrate a
⁵⁹ positive relationship between average summer temperatures and excess all-cause mortality [8, 9,
⁶⁰ 10] with varying thresholds based on region. Public warning systems for heat are targeted toward
⁶¹ managing specific events. Response activities for such heat events were formalized as part of
⁶² relatively recent efforts, primarily in cities like Chicago, Milwaukee, and Philadelphia following
⁶³ deadly heat waves in the early and mid 1990s [11, 12].

⁶⁴ The events led to greater attention on individual and population level factors affecting heat vul-
⁶⁵ nerability [13]. These include age, social isolation, housing type, income, and ethnicity [14, 15].
⁶⁶ Adaptive capacity of individuals is a key determinant in whether, and to what degree, hazards of
⁶⁷ climate change will result in adverse health effects [16]. Understanding vulnerabilities to heat
⁶⁸ has led to efforts such as censuses of susceptible populations and door-to-door visits during heat
⁶⁹ events that have been shown to successfully reduce the related excess mortality [12, 17]. These
⁷⁰ approaches tend to be expensive to implement and rely on significant human resources for scaling
⁷¹ up.

72 The most effective protection against hyperthermia in extreme weather is air conditioning (AC).
73 The increased prevalence of this technology is one reason for declining heat-related mortality in
74 the US in spite of increased frequency of heat events [18]. However, reliance on energy-intensive
75 adaptation strategies like AC results in greater energy use and the production of waste heat. Thus
76 such adaptation measures can result in unintended positive feedbacks on global climate change
77 and can exacerbate the urban heat island effect [19].

78 Warning systems are familiar for weather-related hazards including floods, tornados, winds, and
79 severe storms. As an adaptation strategy they are important for quickly reaching large numbers
80 of people at low cost, and providing targeted messaging that can help minimize damages. Heat
81 warning systems have been shown to save lives during extreme heat [11], but have received less
82 attention than other natural disasters, in part, due to the fact that there is little aftermath (partic-
83 ularly property damage) to heat events. Even when the public is aware of warnings and climatic
84 conditions, there is often far less awareness of what protective actions should be taken [20].

85 *b. The National Weather Service Warnings*

86 Currently the NWS uses four products based on the heat index (HI) – a metric combining tem-
87 perature and relative humidity to describe heat stress and discomfort – to issue hazard notifications.
88 Estimates of temperatures and humidity are predicted days in advance by NWS models which are
89 currently available at a spatial resolution of 2.5 km. Regional offices of the NWS issues statements
90 on the weather and potentially hazardous conditions

91 **Excessive Heat Outlook** : may be issued 3 to 7 days prior to a heat episode requiring issuance of
92 a Heat Warning, provided forecaster confidence is relatively high

⁹³ **Excessive Heat Watch** : may be issued 12 to 48 hours prior to heat episode with a 50 percent
⁹⁴ chance or greater of daytime heat indices equal to or greater than 110 degrees for at least two
⁹⁵ consecutive days.

⁹⁶ **Heat Advisory** : is issued in the first and/or second period when there is an 80 percent chance or
⁹⁷ greater of daytime heat indices equal to or greater than 105 degrees (40.6°C) for at least two
⁹⁸ consecutive days.

⁹⁹ **Excessive Heat Warning** : is issued in the first and/or second period when there is an 80 percent
¹⁰⁰ or greater of daytime heat indices equal to or greater than 110 degrees (43.3°C) for at least
¹⁰¹ two consecutive days.

¹⁰² Some of the main criticisms of the NWS's advisory guidelines relate to their uniformity for
¹⁰³ places across the country. In this respect they have not been representative of regional behavioral
¹⁰⁴ adaptation practices. This leads to warnings and advisories in some areas that may be issued too
¹⁰⁵ frequently or not frequently enough and do not represent actual weather-related risks for people.

¹⁰⁶ In both cases the issuances may lead to skepticism and neglect for the NWS notifications and
¹⁰⁷ decrease their effectiveness. In recent years some regions, like Chicago, have been more proactive
¹⁰⁸ about defining their own criteria not only for daytime high HI as well as nighttime low HI.

¹⁰⁹ Other concerns with the NWS advisories and warnings relate to urban areas where anthro-
¹¹⁰ pogenic land cover modifications may elevate temperatures dangerously high even outside periods
¹¹¹ of regional extreme weather. Hazardous thermal conditions may also exist in small pockets of the
¹¹² urban landscape, which displays great variability in temperatures over space. The current NWS
¹¹³ notification system is based on ???large grid??? climate model and releases warnings and advi-
¹¹⁴ sories at the county level. Because counties vary in size from place to place and may or may not
¹¹⁵ wholly contain major population centers, the NWS products may fail to provide specific warnings

¹¹⁶ and meaningful guidance for large numbers of people. Even if the products are accurately predict-
¹¹⁷ ing regional hot weather, detail to the spatial distribution of temperatures within the region could
¹¹⁸ improve warnings, individual adaptation measures, and larger response efforts.

¹¹⁹ Previous work has examined whether the HI values used are indicative of health threats by
¹²⁰ comparing HI values and mortality for various locations[21, 22] Like the NWS products the HI
¹²¹ values are often collected at a single site used as representative for the entire region. The NWS
¹²² products themselves have also been compared with mortality and morbidity rates in places. The
¹²³ outcome of such studies has shown that HI can be a useful metric for informing decisions to protect
¹²⁴ public health in some locations. Alternatives based on weather classifications, like the Synoptic
¹²⁵ Spatial Classification (SSC), have also been examined for agreement with variability in mortality.
¹²⁶ The NWS system has also been compared against public perceptions of heat risk, a determining
¹²⁷ factor in whether precautionary actions are taken, and found to vary between regions and across
¹²⁸ age, income, gender, and ethnicities within regions [23].

¹²⁹ *c. New Data Sources*

¹³⁰ In situ and remote sensors of temperature at or near the Earth's surface offer the potential to
¹³¹ improve the current warning system by increasing its specificity, particularly with regard to loca-
¹³² tion. These data sources are new and numerous. They provide data with greater spatial coverage,
¹³³ frequent revisit times, and low cost. Distributed weather stations may have a shorter history than
¹³⁴ reliable long term stations used in climatological studies, but can effectively describe spatial pat-
¹³⁵ terns in temperatures across the urban landscape. Imagery products like MODIS's land surface
¹³⁶ temperature (LST) offer 1km spatial resolution data for areas around the globe twice daily. Such
¹³⁷ products are systematically processed to remove inconsistencies and distortions, as well as to cal-
¹³⁸ culate usable temperature outputs. While these data can not currently offer predictive weather

¹³⁹ information, they are nonetheless useful for analyzing and describing spatial variation and pat-
¹⁴⁰ terns which, when combined with predictive models currently in use, can improve information to
¹⁴¹ the public and the adaptive response.

¹⁴² To our knowledge, we are the first to consider spatial variability in the NWS heat warning system
¹⁴³ inside of the regional or county boundary, and the first to compare the National advisory system
¹⁴⁴ to land surface temperatures.

¹⁴⁵ *d. Hypotheses*

¹⁴⁶ In this work we test two primary hypotheses. First, actual data from local stations will exhibit
¹⁴⁷ the conditions for heat warnings at the same time and place as NWS forecasted warnings. We
¹⁴⁸ expect to find that the NWS advisories miss some instances where hazardous heat conditions are
¹⁴⁹ met at locations within counties. We will examine some of the characteristics of such locations,
¹⁵⁰ should they exist. Second, satellite derived land surface temperatures (LST) near weather stations
¹⁵¹ are equivalent to air temperatures recorded at the stations. We expect to find that LST and station
¹⁵² records are well correlated, particularly on NWS-determined advisory days. This would suggest
¹⁵³ that satellite data may provide a means of identifying hazardous heat conditions where stations
¹⁵⁴ do not exist and at scales finer than forecast models. The findings from these tests are expected
¹⁵⁵ to improve the existing national heat warning system by demonstrating the need for sub-county spec-
¹⁵⁶ ification that the current system misses and by providing evidence for how existing data sources
¹⁵⁷ could be used to complement the current NWS system.

158 **3. Methods**

159 *a. Study Locations*

160 This study focuses on two metropolitan areas in different climatic zones of the US: Atlanta,
161 GA and Chicago, IL see Figure a. Atlanta is an inland city in the southeastern US (centered near -
162 84.37, 33.74). Atlanta's historic downtown and central city are located primarily in Fulton County.
163 A portion of the city sits in Dekalb County east of Fulton. Three other counties (two north and one
164 south of the city) were included in the analysis to cover the core of the metropolitan area: Clayton,
165 Cobb, and Gwinnett. Chicago is in the midwest and sits on the large water body of Lake Michigan
166 (centered near -87.63, 41.89). The City of Chicago sits within Cook County. Four surrounding
167 counties (DuPage to the west, Lake, IL to the north, Will to the southwest, and Lake, IN to the
168 southeast were also included in the analysis of the Chicago Metro area.

169

170

¹⁷¹ b. *Heat Advisory Data*

¹⁷² As the historical record of heat warnings, we used NWS-issued Heat Advisories and Excessive
¹⁷³ Heat Warnings. Text records of the statements issued by NWS stations are archived and maintained
¹⁷⁴ by the National Oceanic and Atmospheric Administration's (NOAA) National Climatic Data Cen-
¹⁷⁵ ter (NCDC). The data are stored in the Hierarchical Data Storage System (HDSS), which includes
¹⁷⁶ a tape robotics system for data archived on tape. NCDC provides direct online access to these data
¹⁷⁷ through the HDSS Access System (HAS). Records for the NWS stations responsible for the Atlanta
¹⁷⁸ (KFFC - Peachtree City-Falcon, GA) and Chicago (KLOT - Lewis University, IL) Metropolitan
¹⁷⁹ Areas. Specifically, records heat advisories and excessive heat warnings are contained in Non-
¹⁸⁰ Precipitation Watches, Warnings, Advisories Bulletins (Bulletin ID WWUS7) and are accessible
¹⁸¹ through the Service Records Retention System (SRRS) Text Products/Bulletin Selection interface
¹⁸² (<http://has.ncdc.noaa.gov/pls/plhas/HAS.StationYearSelect>).

¹⁸³ Text files compilations of Bulletins were obtained for May 1- Sep 30 for the years 2006-2012.
¹⁸⁴ Individual text files were combed to identify mention of 'HEAT' and further examined to deter-
¹⁸⁵ mine the day-county for which Heat Advisories or Excessive Heat Warnings applied.

¹⁸⁶ c. *Weather Station Data*

¹⁸⁷ Measurements from weather stations serve as diagnostics of whether or not a hazardous heat
¹⁸⁸ event actually occurred for a given location and day. Two data sources were used for weather
¹⁸⁹ station data. First, temperature and humidity data from NCDC's Surface Data, Hourly Global
¹⁹⁰ (DS3505) data were obtained for Atlanta Hartsfield International Airport (USW00013874) and
¹⁹¹ Chicago O'hare International Airport (USW00094846) from the NCDC website (<http://www.ncdc.noaa.gov/cdo-web/datasets/>). Second, weather station data archived through a net-
¹⁹² work of personal weather stations were aggregated. Weather Underground, a commercial weather
¹⁹³

194 service provider, established the personal weather station network, which they use to inform their
195 BestForecast® system. The Weather Underground network allows individuals to share real-time
196 weather information recorded by personal weather stations. The measurement intervals for stations
197 range between 1 to 60 minutes and differ between stations. The historical record of meteorologi-
198 cal parameters, temperature (°F) and relative humidity (%), from 47 stations in five counties in the
199 Atlanta metro area and 152 stations in five counties in the Chicago metro area, were obtained from
200 the Weather Underground website (<http://www.wunderground.com/>). Stations within the ten
201 counties were queried for hourly temperature and humidity data back to May 2006. These data
202 were collected for Atlanta in September 2013 and for Chicago in October 2013. Since the Weather
203 Underground network is steadily expanding the exact set of stations used in this analysis may differ
204 from the set, if assembled presently.

205 To control the quality of data and eliminate outliers, for each city, we removed observations
206 exceeding the range of mean \pm five standard deviations. For each station, days with less than
207 16 hours valid hourly data and years with less than 75% valid daily data were also excluded to
208 eliminate possible sampling bias. The hourly average temperature and relative humidity values
209 were processed to calculate the HI based on algorithms provided by the NWS (http://www.hpc.ncep.noaa.gov/html/heatindex_equation.shtml). To evaluate if stations experienced
210 hazardous heat conditions, the NWS definition of Heat Advisory was used, such that if there are at
211 least two consecutive days with at least one hourly HI greater than 105 °F (40.6 °C) in each day,
212 these days will be marked as heat wave days.

²¹⁴ *d. Land Surface Temperature Imagery*

²¹⁵ The potential for regularly collected satellite data to provide more information on within-county
²¹⁶ variability in hazardous temperatures is examined through images from May through September
²¹⁷ 2006-2012 in the Atlanta and Chicago Metropolitan cores.

²¹⁸ **4. Results**

²¹⁹ *a. Data Descriptions*

²²⁰ Among records from the airport and Weather Underground weather stations There are 26,943
²²¹ and 70,312 valid station-day data records in total for Atlanta and Chicago, respectively. In total
²²² 1,172 and 1,499 station-days were marked as heat wave days.

²²³ *b. Comparing NWS and Station Data*

²²⁴ *c. Comparing Imagery and Temperatures*

²²⁵ **5. Discussion**
